

Cybersecurity Internship

Strengthening Security Measures for a Web Application

Week 1: Security Assessment

1. GitHub clone:

```
File Actions Edit View Help
(kali@kali)-[~/Desktop/internship]
$ node -v
v22.21.1
$ npm -v
9.2.0
(kali@kali)-[~/Desktop/internship]
$ git clone https://github.com/SirAppSec/vuln-node.js-express.js-app.git
Cloning into 'vuln-node.js-express.js-app' ...

remote: Total 466 (delta 60), reused 55 (delta 55), pack-reused 396 (from 2)
Receiving objects: 100% (466/466), 4.45 MiB | 3.54 MiB/s, done.
Resolving deltas: 100% (202/202), done.
(kali@kali)-[~/Desktop/internship]
$ cd vuln-node.js-express.js-app
```

2. Website pages:

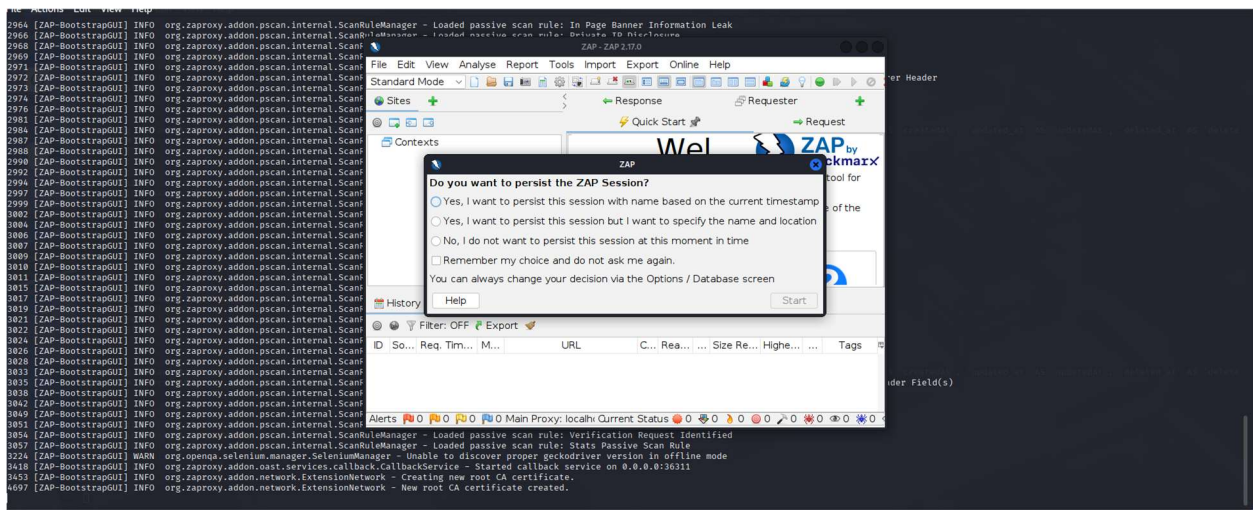

3. Check the signup, login, and profile pages.

I explored the application's Dev Tools

4. OWASP ZAP:

5. Browser Developer Tools: XSS attacks

```

SQL> SELECT 'id', 'email', 'profile_pic', 'password', 'role', 'address', 'name', 'created_at', 'updated_at', 'deleted_at'
FROM (user WHERE (user.deleted_at IS NULL AND user.email = '<script>alert(''XSS'')</script>'));

```

[illegible]

```
<script>alert('XSS')</script>
```

6. Basic SQL Injection Test

Attempted authentication bypass using SQL injection payload:

admin' OR '1'='1

The application did not authenticate the user. The ORM (Sequelize) escaped the payload, preventing SQL execution. The application is not vulnerable to classic SQL Injection attacks. However, the application does not validate or reject malicious input, which may lead to other injection-based attacks such as XSS.

Week 2: Implementing Security Measures

1. Fix Vulnerabilities

- Sanitize and Validate Inputs: validator

```
*/
app.post('/v1/user/', async (req, res) => {

  //const userEmail = req.body.email || '';
  const userEmail = validator.normalizeEmail(req.body.email || '');
  //const userName = req.body.name || '';
  const userName = validator.escape(req.body.name || '');
  const userRole = req.body.role || 'user';
  //const userPassword = req.body.password || '';
  const userPassword = validator.escape(req.body.password || '');
  const userAddress = validator.escape(req.body.address || '');

  // Email validation (basic + crash safe)
  if (!validator.isEmail(userEmail)) {
    return res.status(400).json({ error: 'Invalid email format' });
  }

  // Password length check
  if (userPassword.length < 6) {
    return res.status(400).json({ error: 'Password must be at least 6 characters' });
  }

  try {
    // Hash password
    const hashedPassword = await bcrypt.hash(userPassword, 10);

    const new_user = await db.user.create({
      name: userName,
      email: userEmail,
      role: userRole,
```

The validator library was implemented to validate and sanitize user input, especially email fields and query parameters. Invalid input is now rejected before being processed by the application, preventing crashes and injection attacks.

- Password Hashing: Use bcrypt to hash

```
(kali@kali)-[~/Desktop/internship/vuln-node.js-express.js-app/db]
$ sqlite3 db.sqlite
SQLite version 3.46.1 2024-08-13 09:16:08
Enter ".help" for usage hints.
sqlite> .tables
beer_users  beers      users
sqlite> SELECT id, email, password FROM users;
1|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
2|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
3|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
4|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
5|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
6|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
7|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
sqlite> DELETE FROM users;
sqlite> SELECT id, email, password FROM users;
sqlite> SELECT id, email, password FROM users;
sqlite> SELECT id, email, password FROM users;
1|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
sqlite> SELECT id, email, password FROM users;
1|monster123@gmail.com|bc6a9ce7752e15bf81aeb07a9fb678
2|monster123@gmail.com.pk|bc6a9ce7752e15bf81aeb07a9fb678
sqlite> DELETE FROM users;
sqlite> SELECT id, email, password FROM users;
sqlite> SELECT id, email, password FROM users;
sqlite> SELECT id, email, password FROM users;
1|monster123@gmail.com|$2b$10$Gawcjvjd7kCfKyMmld5dXexQvUJYQp1T3WUraLUPMEq27MHdycLpC
2|monster123@gmail.com.pk|$2b$10$gf0gB6Yq6YhiQ6VPVboWVe2ajs8WQDBJPuOu3XrcKnRP9DB/riMau
sqlite>
```

Passwords were secured using bcrypt. User password are now hashed and salted before being stored in the database, ensuring that plaintext credentials are never saved. The password were firstly stored in MD5 which was changed to bcrypt.

2. Enhance Authentication

```
8 module.exports = (app,db) => {
9
10
11 function verifyToken(req, res, next) {
12
13     const token = req.session.token;
14
15     if (!token) {
16         return res.redirect('/?message=Authentication required');
17     }
18
19     try {
20         const decoded = jwt.verify(token, JWT_SECRET);
21         req.user = decoded; // attach user info
22         next();
23     } catch (err) {
24         return res.redirect('/?message=Invalid or expired token');
25     }
26 }
27
```

```
* @param {string} profile_description
*/
app.get('/profile', verifyToken, (req,res) =>{
```

Basic token-based authentication was implemented using JSON Web Tokens (JWT). After successful login, a signed token is issued to the user and used for authentication in protected routes. This improved session handling and reduced reliance on insecure session mechanisms.

3. Secure Data Transmission

```
'user strict';
const helmet = require('helmet');
const express = require('express'),
    //morgan = require('morgan'),
    config = require('./config'),
    router = require('./router'),
    bodyParser = require('body-parser'),
    db = require('./orm')

const sjs = require('sequelize-json-schema');

const app = express()
const PORT = config.PORT;
//OPTIONAL: Security headers????
// app.use((req, res, next) => {
//   res.header('Content-Type', 'application/json');
//   res.header("Access-Control-Allow-Origin", "*");
//   res.header("Access-Control-Allow-Methods", "GET, POST, PUT, PATCH, DELETE");
//   res.header("Access-Control-Allow-Headers", "Origin, X-Requested-With, Content-Type, Accept");
//   next();
// });

//OPTIONAL: Activate Logging
// app.use(morgan('combined'));
app.use(helmet());
app.use(bodyParser.json());

//session middleware
var cookieParser = require('cookie-parser');
```

```
File Actions Edit View Help
(kaliⓈkali)-[~/Desktop/internship/vuln-node.js-express.js-app]
$ curl -X POST http://localhost:5000/v1/user \
-d '{"email":"aaa@", "password":"123"}'
{"error":"Invalid email format"}
```

Although the application runs on HTTP in a localhost environment, HTTPS readiness was verified. Security headers such as HSTS were enabled using Helmet. This ensures the application can be deployed securely behind a TLS-enabled proxy in production environments.

Week 3: Advanced Security and Final Reporting

1. Basic Penetration Testing

- Use tools like Nmap or browser-based testing to simulate common attacks.

```
kali@kali:~/Desktop/internship/vuln-node.js-express.js-app$ nmap -sC -sV -p 5000 localhost
Starting Nmap 7.95 ( https://nmap.org ) at 2026-01-12 03:04 EST
Nmap scan report for localhost (127.0.0.1)
Host is up (0.0001s latency)
Other addresses for localhost (not scanned): ::1

PORT      STATE SERVICE VERSION

```

An Nmap scan was conducted using default scripts and version detection. The application exposed only one TCP port (5000), which minimized the attack surface. Service fingerprinting was inconclusive, which is typical for custom Node.js applications. Security headers such as CSP, HSTS, and X-Frame-Options were detected, confirming successful implementation of browser-level protections.

The above demonstrates a Reflected Cross-Site Scripting (XSS) attack on the application. By supplying the payload `<script>alert(1)</script>` through the message URL parameter, the application rendered the input directly into the response without proper output encoding. This caused the browser to execute the injected JavaScript and display an alert dialog, confirming that arbitrary client-side code can be executed in the context of the user's session.

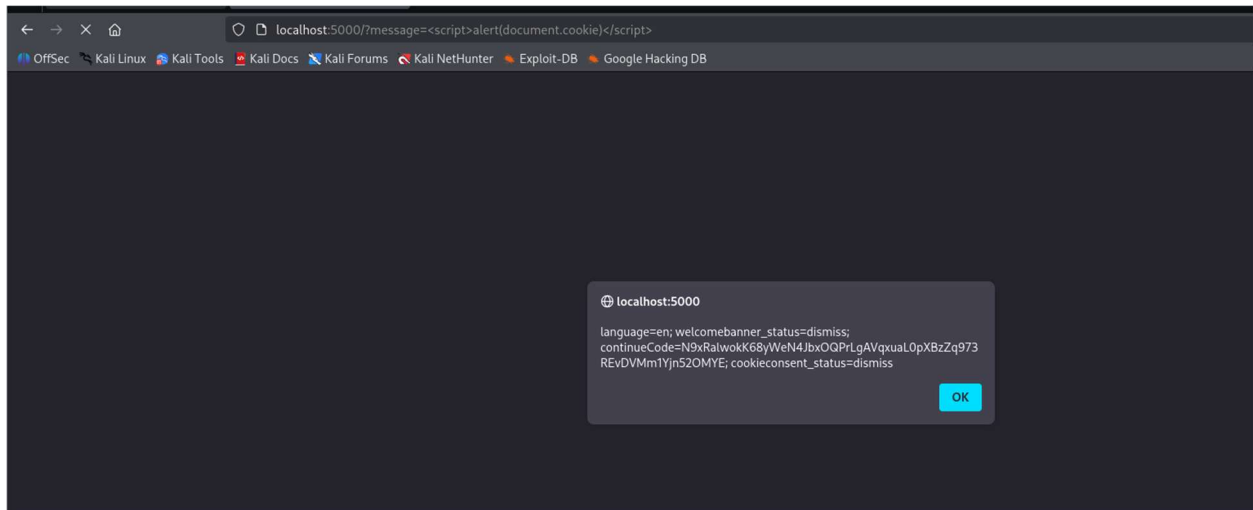

In this the payload `{{7*7}}` was evaluated by the application and rendered as 49, indicating the presence of a Server-Side Template Injection (SSTI) vulnerability.

This demonstrates a more advanced Server-Side Template Injection (SSTI) payload using `{{range.constructor('return process.env')}}}}`, which resulted in the output `[object Object]`.

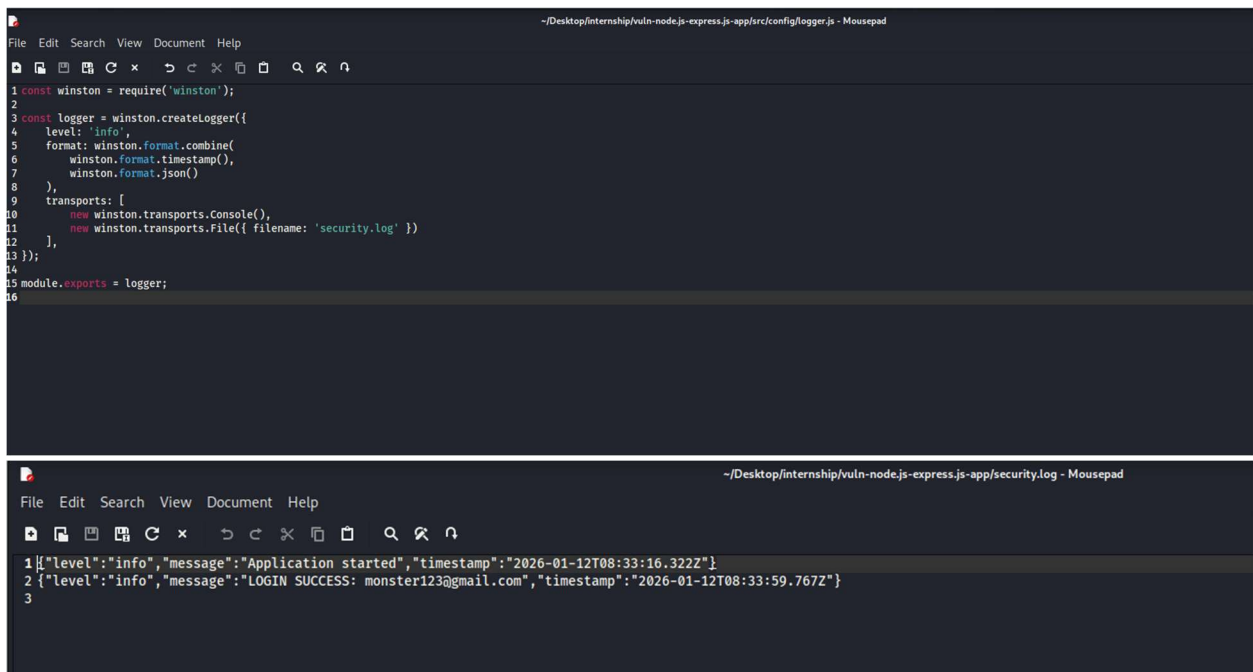

This represents a high-risk vulnerability, as it may lead to sensitive information disclosure and, in some cases, remote code execution if the attacker is able to further manipulate the execution context.

2. Set Up Basic Logging

The application already had a logging system setup, but as required another similar one was setup using Winston.

3. Create a Simple Checklist

1. Application-Level Security

- Input validation using the validator library
- Proper handling of undefined or malformed inputs to prevent crashes
- Improved error handling to avoid server crashes (DoS prevention)

2. Authentication & Authorization

- Password hashing and salting using bcrypt
- Secure password storage
- JSON Web Token (JWT)–based authentication
- Protection of sensitive routes using authentication middleware

3. Session & Client-Side Security

- Inspection and hardening of cookies and session data
- Reduced exposure of sensitive identifiers in client-side code

4. Transport & HTTP Security

- HTTPS readiness verified for production deployment
- Security headers implemented using Helmet:
 - Content Security Policy (CSP)
 - HTTP Strict Transport Security (HSTS)
 - X-Frame-Options
 - X-Content-Type-Options
